Abstract

Background: Anemia is a condition characterized by reduction in the number of red blood cells and/or hemoglobin (Hb) concentration. Anemia is a global public health problem affecting both developing and developed countries and has major consequences for human health as well as social and economic development. **Objectives:** To study the prevalence and sociodemographic correlates of anemia among Adolescent (13-19 years) girl students **Methodology:** The present study cross sectional study was conducted among 200 adolescents (13 – 19 years) girls studying 8std -12std in government school Raichur. The data collected was entered in Microsoft excel and analyzed using epi-info software and SPSS trial version 17. **Results:** Mild anemia (Hb 11 – 11.9gram percent) was present in 8 (16%) girls, moderate anemia (Hb 7 – 10.9 gram percent) in 37 (74%) girls and severe anemia (Hb < 7 gram percent) in 5 (10%) girls. About 116(58%) were between 17-19 years of them 28 (24.2%) had anemia. There was association between anemia and socioeconomic status, anemia and type of family in our study. 32% had illiterate father compared to 68% literate father with p value 0.034 (which is not statically significant), but majority of them i.e 84% had illiterate mother and only 16% had literate mother. **Conclusion:** Anemia prevalence is noted in our study as 25% with moderate anemia as 74%. Microcytic hypochromic anemia 60% was noted followed by normocytic normochromic 30%, macrocytic normochromic 10%. High risk factors were students belonging to low socio – economic groups.

INTRODUCTION

The word Adolescence is derived from a Latin word “adolescere” which means “to grow”. WHO defines Adolescent as a person between 10 and 19 years of age.¹ There are 1.2 billion adolescents (10 – 19 years) worldwide² and India is home to the largest national

population of adolescents (243 million), followed by China (207 million), the United States (44 million), Indonesia, and Pakistan (both 41 million each).³ World health organization also defines Adolescent as a transitional period phase of growth and development between childhood and adulthood.⁴ Adolescence is a crucial period in life of every individual, during which there is a transition from childhood to adulthood. This period is characterized by rapid physical, biological, and hormonal changes resulting in psycho-social, behavioral changes and sexual maturity in an individual. It is the second growth spurt of life, and both boys and girls undergo different experiences in this phase.^{5,6}

Anemia is a condition characterized by reduction in the number of red blood cells and/or hemoglobin (Hb) concentration.⁷ Anemia is a global public health problem affecting both developing and developed countries and has major consequences for human health as well as social and

economic development. It affects 24.8% of the world population.⁸ The burden of anemia varies with a person's age, sex, altitude, and pregnancy.⁷ The worldwide prevalence of anemia among adolescents is 15% (27% in developing countries and 6% in developed countries).⁹

Objectives:

To study the prevalence and sociodemographic correlates of anemia among Adolescent (13-19 years) girl students

Source of data: The present study was conducted among 200 adolescents (13 – 19 years) girls studying 8std -12std in government school Raichur, with the aim of finding prevalence of anemia and associated risk factors

Study design: Cross – sectional study

Study area: Government school girls – Raichur

Study population: Adolescent (13 – 19 years) girl students

Sample size: 200

Calculated using the formula, $N = 4pq/L^2$

(Where N = Sample size, p = prevalence of the condition, q = 100 – p, L = allowable error, taken as 5 here)

From the recent study in Karnataka, prevalence of anemia among adolescents was 89%

Hence $N = 4 \times 89 \times 11 / 5 \times 5$

= 3916 / 25

= 157

It was rounded off to 200 including a non – response rate of 20%.

Hence the total sample size is taken as **200**

Inclusion criteria:

1. Adolescent girls aged 13 – 19 years

Exclusion criteria:

1. girls who were unavailable for data collection during 3 consecutive visits
2. Those girls who did not consent for the study.

Data collection:

- The study is conducted after taking Ethical community clearance, consent from the government school principal.
- Counselling was done first, after that proforma were given to the students.
- A predesigned pretested Proforma was used to collect data. It contained identification details, socio – demographic details and clinical details.
- Proforma was given to the students which contained the questioners regarding the socio-demography and clinical factors associated with anemia, it was explained in verbal language, then students were asked to complete it and completed proforma was taken for analysis.
- Statistical plan: The data collected was entered in Microsoft excel and analyzed using epi-info software and SPSS trial version 17. The categorical variables are expressed as percentage and relation between two categorical variables are analyzed using Chi – square test.

RESULTS

Table 1: Prevalence of anemia

Parameters	Number of cases	Percentage
Mild anemia	8	16%
Moderate anemia	37	74%
Severe anemia	5	10%

Anemia was present in 50 (25%) of the study participants. Mild anemia (Hb 11 – 11.9 gram percent) was present in 8 (16%) girls, moderate anemia (Hb 7 – 10.9 gram percent) in 37 (74%) girls and severe anemia (Hb < 7 gram percent) in 5 (10%) girls.

Table 2: Comparison of socio – demographic factors associated with anemia

Factors	Number (N=200) (%)	Anemia (N = 50) (%)	No anemia (N= 150)(%)	Chi – square (χ^2)	'P' value
Age :- 13 – 16 years	84 (42%)	22 (26.2 %)	62 (73.8%)	7.111	0.328
17 – 19 years	116 (58%)	28 (24.2 %)	88 (75.8%)		
Education :- 8std	24(12.0%)	04 (16.6 %)	20 (83.4%)	2.642	0.852
9std	35(17.5%)	12 (34.2 %)	23 (65.8%)		
10std	42(21.0%)	16 (38.1 %)	26 (61.9%)		
11std	55(27.5%)	09 (16.4%)	46 (83.6%)		
12std	44(22.0%)	09(20.5%)	35 (79.5%)		
Religion :- Hindu	165(82.5%)	44 (26.7 %)	121 (73.3%)	1.401	0.496
Muslim	17(08.5%)	03 (17.6%)	14 (82.4%)		
Christian	18(09.0%)	03 (16.7%)	15 (83.3%)		

About 116(58%) were between 17-19 years of them 28 (24.2%) had anemia and 84(42%) were between 13-16 years of them 22 (26.2 %) had anemia , and P value was not found statistical significant. About 24 (12%) girls were studying in 8std out of which 4 (16.6%) had anemia and 35(17.5%) were studying in 9std of which 12 (34.2%) had anemia. About 42(21%) girls were studying in 10th std of which 16(38.1%) had anemia and 55 (27.5%) girls were studying in 11th class

out of them 9(16.4%) had anemia and 44 (22%) in 12th class of which 9 (20.5%) had anemia , P value was not found statistical significant, may be because of small number

- Majority of the girls were Hindus, 165 (82.5%) while 18 (9%) were Christians and 17 (8.5%) were Muslims, no correlation of anemia with religion was noted in our study (No significant p value)

Table 3: Comparison of socio – demographic factors associated with anemia

Factors'	Number of cases (N=200)	Anemia (N=50)	No anemia (N=150)	Chi value square (χ^2)	P value
Socio – economic status					
Upper class- I	01(00.5%)	00 (0)	01 (100.0)		
Upper middle class -II	40(20.0%)	08 (20.0%)	32 (80.0%)		
Lower middle class-III	55(27.5%)	06 (10.9%)	49 (89.1%)	14.281	0.006
Upper lower class- IV	78(39.0%)	24 (30.8%)	54 (69.2%)		
Lower class - V	26(13.0%)	12 (46.2%)	14 (53.8%)		
Type of family					
Nuclear	130(65.0%)	19 (14.6%)	111 (85.4%)		
Joint	47(23.5%)	22 (46.8%)	25 (53.2%)	21.848	0.000
Extended joint	23(11.5%)	09 (39.1%)	14 (60.9%)		

In our study we noted that according to Socio-economic status , about 78 (39%) girls belonged to class IV next being 55 (27.5%) belonging to class III, combining class III- IV was only 41.7% were anemia, only class V had 12 i.e., 46.2% , significant P value is found , which indicated high prevalence of anemia is more among Lower class followed by upper lower class. Majority of the girls, 130 (65%) belonged to nuclear families, 47 (23.5%) to joint families and 23 (11.5%) to extended joint families, and P value was not found statistically significant.

Table 4: Comparison of parent's education with anemia

Parameters	Father		P value	Mother		P Value
	Illiterate N= 38	Literate N=162		Illiterate N=186	Literate N=14	
Anemia (50)	16(32%)	34(68%)	0.034	42(84%)	8(16%)	0.230
No Anemia (150)	22(14.6%)	128(85.4%)	0.052	144(96%)	6(4%)	0.023

In our study 50 cases were anemic among these 16 (32%) had illiterate father compared to 34 (68%) literate father with p value 0.034(which is not statically significant), but majority of them, that is 42 (84%) had illiterate mother and only 8(16%) had literate mother. This signifies that mother's education plays an important role in prevalence of adolescent students' anemia, as she is directly involved in managing the nutritious status of adolescent's girls however p value was not statically significant. In case of 150 non- anemia cases 128 (85.4%) father were literate and 6(4%) mother were Literate, signifies that father education may also play role in prevention of anemia, might be by affecting the economic status of the family.

Overall, both parent's education signifies the nutritious status of adolescent girls by influencing both economic and nutritional status.

DISCUSSION

The prevalence of anemia in the present study was 25%, which is similar to the prevalence in developing countries (27%).⁹ Many other studies have showed varying prevalence of anemia in India. Chandrakumari, *et al.* (2019)¹⁰ found a prevalence of 48.63% among adolescent girls in a rural area of Tamil Nadu. Patil N *et al.* (2018)¹¹

found that the overall prevalence of anemia was 44.4% among adolescent girls in North Karnataka. Melwani V *et al.*(2018)¹² reported that anemia was present in 57.65% girls amongst adolescent girls residing in slum of Bhopal city. Ayushi Agrawal *et al.*(2018)¹³ reported a prevalence of 45.7% among adolescent girls in a coastal district of India. Patel S, Dhuppar P, Bhattar A (2017)¹⁴ conducted a study on nutritional anemia status in adolescent girls in rural schools of Raipur and found a 36.4% prevalence of anemia. The prevalence of anemia was 36.59% in a study conducted by Gurpreet Singh, Kuldip Singh (2017)¹⁵ in urban college going girl students, whereas in a study by Bhagyalaxmi Sidenur, Gowri Shankar (2017)¹⁶, anemia was present in 89% of adolescent girls. Mean age of the study participants in the present study was 16.65±1.96 years. In a study by Patil N *et al.*¹¹ mean age were 14.34±1.8 years. Another study by Melwani V *et al.*¹² in Bhopal city showed that mean age of the study participants was 15.2±2.5 years. In the present study, prevalence was significantly more in girls belonging to lower socio – economic class, 12 (46.2%) compared to other socio – economic groups. Also, the higher the socio – economic class, the lower was the prevalence of anemia ($\chi^2 = 14.281$, $p = 0.006$). The reason for this could be the availability of

better quality of food in higher socioeconomic classes. This is in consistence with a study by Chandrakumari, *et al.*,¹⁰ which showed that the prevalence of anemia was significantly high (70.59%) among the girls who belonged to class V, followed by class IV (50.49%) and class III (34.48%), similarly, a study by Arya AK, Lal P, Kumar N, Barman S.¹⁷ showed that higher percentage of anemia was found in lower socio – economic class (85.3%) and upper lower class (83.3%). No participant belonged to upper class in the study. Even in a study by Srivastava A, Kumar R, Sharma M,¹⁸ anemia was found to be significantly associated with low socioeconomic status, increased family size and lower levels of parental education.

CONCLUSION

25% prevalence is noted in our study which is of moderate magnitude. Moderate anemia was most commonly found in our study that is 74%. On peripheral smear, most commonly microcytic hypochromic anemia 60% was noted followed by normocytic normochromic 30%, macrocytic normochromic 10%. High risk factors were students belonging to low socio – economic groups
